This topic demands an interdisciplinary focus since an adequate synthesis of the scientific information available includes at least the fields of architecture and interior design, psychology, sociology, anthropology, and geography. Although reaching consensus across such a diversity of theoretical orientations and approaches is difficult, several useful points can be defended within this broad review. Evidence suggests that even our memories are divided into context-dependent and context-independent varieties, so both the physical and social environment have an impact on human achievement.

First, the physical environment can influence the social and task interactions among the people in it. Primarily this influence involves relative accessibility of interaction and the psychological and social interpretation of such interactions. For example, physical distance represents a major determinant of social influence. In a study of engineers, the majority of their work-related information came from other people within six feet of their primary work area. Another surprising study showed that the single best predictor of one’s marital partner was proximity.

These results must be balanced by numerous studies demonstrating that the psychosocial “buffer” between individuals and their physical environment plays an important role in determining how that interaction unfolds. How we interpret the intentions and motives of others—as well as how we perceive and understand our environment—can influence the environment’s effect on us just as surely as can its physical features.

Second, the physical environment can interfere with the frequency and quality of social interaction. The importance of nonverbal cues in the facilitation of interactions between and among people has been recognized for some time; more recently, it has been suggested that barriers to these nonverbal cues may reduce the ease and efficiency of communication (for example, in e-mail and teleconferencing), primarily through interfering with the establishment of trust.

Physical Space and Social Interaction
Jay Brand, Ph.D.

A summarization of ways to set up spaces to foster interaction and improve communication in groups. The impacts of various furniture choices and arrangements, windows and lighting are discussed. An extensive annotated bibliography is included.
Third, social interaction and the layout of space reciprocally influence each other. It is thus important to consider the nature and function of work processes within and between groups or teams when designing work areas to support them. Not only should the initiation and implementation of collaborative work be considered, but also its maintenance and coordination over time.

Finally, whether or not the physical environment, in addition to encouraging social interaction, can augment its efficiency remains somewhat controversial. However, there is little doubt that proximity, and ease and availability of social exchange can be affected by the structure of the environment; open spaces, particularly open spaces incorporating symbolic focus points or other directing elements, can facilitate and coordinate the communication so necessary for efficient collaboration within the office.

Some specific recommendations:

1. In general, having windows (as opposed to no windows) in a room increases its social desirability; the bigger they are (between ceiling and floor) the better. Whether windows enhance task efficiency for a room’s occupants remains controversial, although moods and emotional tone can be improved by natural light. Of course, the nature of the task is important when considering windows; for example, intimate behavior is usually not encouraged by windows.

2. In general, if the room is well-lit (ideally with natural light), a high (or sloping) ceiling encourages social interaction.

3. In general, furniture can support and encourage social interaction if its arrangement removes any barriers between and among people (e.g., a circle of chairs would be preferable to lines of desks). The most “unfriendly” arrangement for office furniture involves the traditional “two-dimorphic-chairs-facing-a-desk-between-them” configuration. Of course, how many people need to interact would need to inform furniture configurations as well, and the broader culture influences what individuals consider “friendly” or “unfriendly.”

4. With some exceptions, couches are less formal than chairs, but their advantages may be mitigated if the group is not acquainted. Furthermore, ergonomic seating considerations become important if tasks involve long time periods.

5. To maximize social exchange, furniture should provide no cues to relative status within the group.

6. How people are dressed may interact with what types of furniture and furniture configurations they will find most acceptable. For example, lying around on a big rug may not be comfortable for women wearing miniskirts; they might prefer the group sit around a table facing each other.

7. In general, configurations that allow open, essentially face-to-face orientations with every other member of the group (allowing for individual adjustments) encourage social interaction more than those that do not.

8. In addition to supporting individual work with personal work spaces, work areas should be purposefully organized around the social and collaborative functions occurring in the work place. Efficient communication within teams and coordination/collaboration between teams can be enhanced by a properly configured environment.

9. Group areas may even need more attention paid to social “channeling” and other symbolic details than personal work areas, since 60% of what people learn occurs informally, and much of this happens within teams.

10. The arrangement and configuration of individual workspaces in relation to larger aggregations of work areas for group- and macro-level communication can be informed by a systematic analysis of task and skill coordination needs. At the very least, sagacious designers and facilities managers will create work areas that focus on human performance at all levels of the organization, specifically addressing work group and team needs in addition to possible privacy needs and other individual-level concerns.

Finally, the psychological, sociological, cultural and symbolic features of group processes, group dynamics, and social interaction may be even more important than the structure of the environment in determining the nature of social exchanges. Individual-, group-, and macro-level factors have been identified that constrain the nature of conversations between people, and the general efficiency and maintenance of communication. Discovering precisely how best to support rewarding and productive social interaction with the physical environment may require more knowledge of how complex, reciprocally determined systems develop and maintain themselves. Self-organizing systems—and modern offices no doubt must be of this type—can produce emergent phenomena that depend critically on initial conditions. Such realities suggest that even small facilities accommodations and flexibility at the level of furniture, components and configurations may have profound organizational effects.
Annotated Bibliography

Explores the implications for social analysis of different “grain”-sized for demographic aggregation; the tradeoffs between micro- and macro-analyses of social dispersion and influence are thus compared.

Evidence that the rewards of social interaction differ between leisure and non-leisure settings; these differences depend in some respects on participants’ gender and age.

Demonstrates that just as spaces influence people, people also influence spaces by altering or changing them. Patterns of social collaboration and group culture must thus be considered when designing for group and team coordination.

Introduces the influential idea that phenomena organized and defined at various group levels can determine the nature of social interaction among individuals.

Argues that social interaction itself constructs a reality that constrains further communication in a self-referential loop.

Argues that since the cognitive effort involved in “retrying” after communication failure is related to message level, communication strategies must be organized hierarchically; however, the number and type of alternative messages generated influences this basic result.

Synthesizes evidence that representations in semantic memory can be subdivided into context-independent and context-dependent information.

Although some information now appears somewhat dated, provides a pertinent, historical overview. See especially M. Wolfe's and H. Proshansky's "The physical setting as a factor in group function and process."

Proposes that culture results from people affecting each other in reciprocal and recursive influence; such social interaction is constrained by physical distance and group-level dynamics operating within a social impact network.

An comparison among dynamic social impact theory (DSIT), Lewin’s “life space,” Blau’s multi-dimensional space, and Moreno’s network analysis.

Research showing that social influence depends critically on physical distance separating the parties involved; also demonstrates several other properties of real social systems, such as the survival of fairly stable minority groups within a majority culture.

Explores the implicit “taking-turns” rules of conversation, arguing that preferences exist for agreement over disagreement, self-over other-correction, and offers over requests.

An earlier reference; see especially chapters 12 and 18.

Outlines the constraint dynamics imposed on social discourse by the structure of different environments at a community-level "grain" (scale) of analysis.

Demonstrates cross-cultural, gender, and age differences in body orientation and touch during conversations.

Develops a theory positing that macro-level influences can constrain group-level interactions so as to preserve social discrepancies throughout the population; computer simulations generally supported this possibility.

Work groups can exhibit non-linear interaction patterns such that hierarchical relationships may not be transitive. Gender does not seem to have any systematic effect on such results.

An excellent general reference; regarding the design of spaces for social interaction, see especially chapters 14, 18, 19, 30, and 53 (particularly 19).

Explores parallels between social representations as self-organizing systems and evolution; argues that aggregate-level phenomena can impact individual behavior.

Hybrid office spaces support both groups and individuals, flexibly accommodating communication among people within the office and with outside contacts.

Group and individual characteristics, and expectations of future interaction influence current communication patterns and efficiency in CMC.

Provides technical specifications and anthropometric data.

The symbolic meanings of office environments influence people’s satisfaction with structural changes; this effect is mediated by level within the organization.
